

# Disaster Management

## 3. Typical Strategy for Pakistan

BY

Dr Engr. Javed Yunas Uppal

[CHAIRMAN@pfaet.com](mailto:CHAIRMAN@pfaet.com)

Pakistan Foundation for the Advancement of  
Engineering and Technology

**Beware of large openings in their ground floor exterior walls, big windows, patio doors, and garage doors**

# Faulty construction on sliding soil: root cause of death in earthquake-hit areas

# Turkey 1999 earthquake: 34 killed in wood frame houses and 40,000 in masonry and concrete

# Sticking out elements fall first

# Drop and cover position

# Buildings that performed better

- A century and half a century old buildings in Murree, Muzafarabad and Balakot, including old barracks of British Army, with a **canopy roof made of iron sheets**, survived and resulted in less damages.
- New buildings using **concrete slabs** were erased to the ground and did not allow rescue teams to rescue trapped people inside buildings because concrete slabs were not only heavy to remove rather difficult to cut or break.
- Muzafarabad President House and Prime Minister House of similar construction have received serious damage.

## Buildings that performed better

- **Abbotabad can be taken as prime example to understand this issue. Abbotabad Cantonment, which was established during British Era, was constructed on Gothic style mostly with canopy rooftops using **wooden pillars**. These buildings have survived while new buildings with **concrete slabs and no seismic frames** have erased to ground.**
- **Mushroom like growth of buildings with structural design similar to plain areas played havoc.**

# Loose masonry

# 1990 Earthquake, Scale 6.0, *Masooleh*, Iran, Resulted Very Minor Damage

- Most buildings, two to three storeyed, made in thick adobe and mud walls, were more than 100 years old.
- Wooden beams, columns and ring ties framed around the walls.

# Masooleh

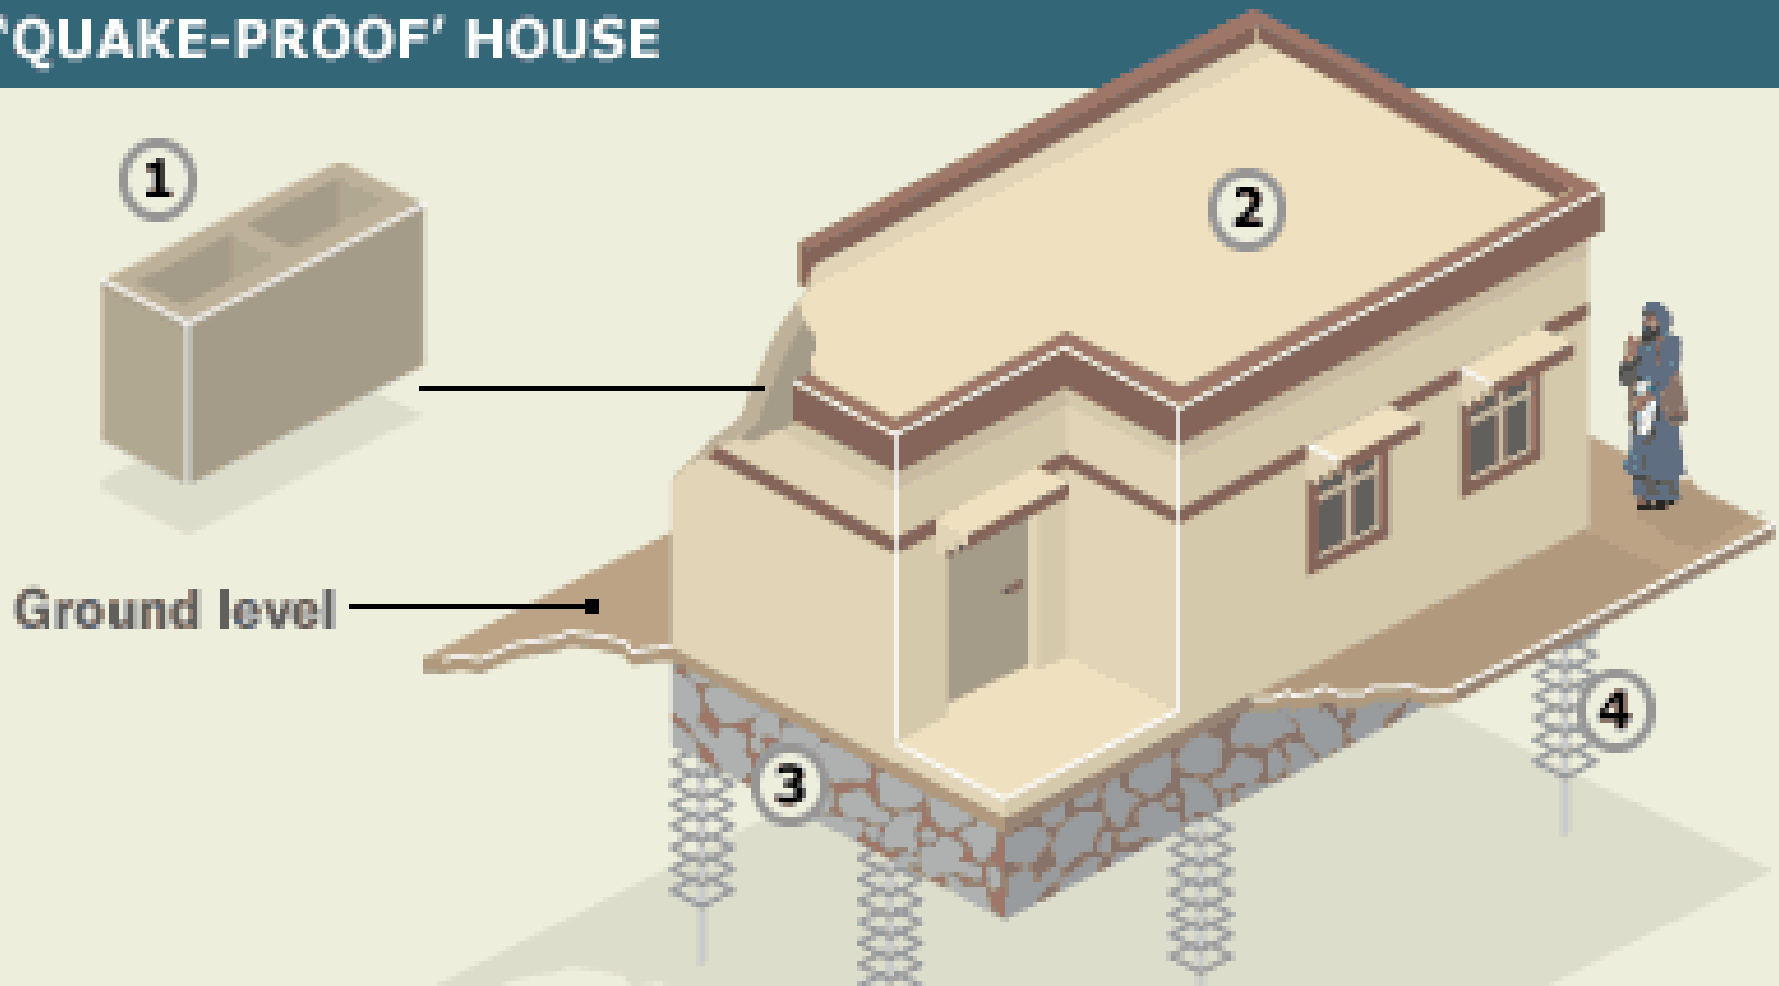

**Many traditional buildings were constructed on base-isolated foundations, with layers of timber enabling rolling movement**

A number of techniques can be used to make houses withstand earthquakes better:

1. **Hollow block walls** designed to cause minimal damage
2. **Low weight** articulated roofs
3. Stone foundations made from **energy dissipating dry rubble**
4. Timber or steel bracings and pillars providing flexibility

## 'QUAKE-PROOF' HOUSE

# Features to be included in design: new construction or a retrofit

- • **Special attention to potential weak ground floors.**
- • **A heavy foundation on stable ground.**
- • **Walls well tied to the foundation.**
- • **Lateral resistance in key walls**
- • **Proper nailing of wood to the studs.**

# Earthquake Proof Buildings

- No building can be completely earthquake-proof, but **good seismic design** will minimize structural damage, and,
- Most importantly, **safe evacuation** of the occupants during an earthquake is a prime factor.

# HOW CAN WE REDUCE EARTHQUAKE LOSSES

- **(1) Understanding the nature and extent of the earthquake risk,**
- **(2) Taking actions to reduce the risks, and**
- **(3) Establishing policy to guide the development of effective risk-reduction programs**
- **(4) Practical steps on earthquake hazard mitigation and preparedness.**

# Understanding Earthquake Risk

- **(1) Risk can be numerically defined as the probability of a hazardous event multiplied by the cost of damage that would result should the event happen.**
- **(2) Maps have to be drawn depicting expected levels of ground shaking, and distribution of physical development.**

# Sociological factors

- **Sociological factors that should be considered in the determination of earthquake risk include:**
- **the distribution of people,**
- **businesses and industries,**
- **financial institutions,**
- **important transportation routes**
- **permanent storage sites, and**
- **location of critical facilities: medical etc.**

# Risk Reduction

- Earthquake damage can be reduced by:
- (a) taking account of earthquake hazards in **land-use** decisions,
- (b) using appropriate engineering and construction **design** to reduce the hazard, and
- (c) **involving communities** in earthquake preparedness programs.

# Land-Use Decisions

- local regulatory laws can encourage suitable types of **land use**.
- restricting development within **easy control**.
- Forming a National Earthquake Hazard Reduction **Program**
- Development and promotion of appropriate building **codes**

# Engineering and Architectural Design

- Engineers have to develop methods to increase the **resistance of land and structures** to the damaging effects of strong ground shaking.
- Stabilization of **landslide** areas and **compaction** of soft-soil sites. Vibro-flotation is one method.
- Provide proper **drains** to keep fields dry.
- Use building **shapes** that do not localize large stresses

# Nonstructural hazards

- Nonstructural hazards can be reduced in new or existing buildings by:
- **Securely attaching** ceiling panels, light fixtures, and shelving and by
- Installing special equipment, like **safety glass** and automatic gas **shut-off valves**.
- Strengthening older buildings

# Earthquake Preparedness Programs

## ***(1) Before an earthquake occurs***

- This means planning:
- What to do to **reduce** earthquake risk,
- What emergency **supplies** should be on hand, and
- What steps to take during and after an earthquake to reduce **loss of life**
- Identifying earthquake hazards, earthquake **drills**, emergency supplies, and shelter management.

# Preparedness Exercises

- identifying areas that are safe from **falling objects**,
- practicing **what to do during** the shaking and
- **What to do** when the **shaking stops**, and
- obtaining essential emergency supplies like a **first aid kit**.
- Doing some preparations, like **securing water and power**.
- Securing **heating** arrangements.

# Earthquake Preparedness Programs

## ***(2) During an earthquake***

- **Strong ground shaking often lasts only 30 to 60 seconds.**
- **Power failures may plunge a room into darkness.**
- **Find a nearby protected place to take shelter until the shaking stops. Take the drop and cover position.**
- **This should be taken under a sturdy desk or table, inside a doorway, along a wall entirely inside a building, or within the inside corner of a room.**
- **Take actions during an earthquake if one is inside a building, outside, or in a vehicle.**

# Earthquake Preparedness Programs

## ***(3) During an earthquake***

- **prevent additional injury and loss of life  
building should be evacuated because  
of the possibility of further damage**
- **hazards like fire or gas leaks have to be  
looked into**
- **occupants should be accounted for  
medical assistance and food supplies**

# What To Do During an Earthquake

<b>Location</b>	<b>Action</b>	<b>Where</b>	<b>Hazards</b>
<i>Inside building</i>	<b>Drop and cover</b>	<b>Under sturdy desk</b> <b>Under sturdy table</b> <b>Along inside wall</b> <b>In doorway</b> <b>In corner</b>	<b>Window glass</b> <b>Overhead objects</b> <b>Objects on wheels</b> <b>Swinging doors</b> <b>Collapsing fireplaces</b> <b>Chimneys</b>
<i>Outside building</i>	<b>Drop and cover (if necessary)</b>	<b>Building entryway (inside, where not subject to material falling from outside walls)</b> <b>In clearing, away from wires other overhead dangers</b>	<b>Building facades</b>  <b>Overhead wires</b> <b>Trees</b> <b>Steep slopes</b>

# What To Do During an Earthquake

<b>Location</b>	<b>Action</b>	<b>Where</b>	<b>Hazards</b>
<b><i>Outdoors, in open</i></b>	<b>Stay in open areas</b>	<b>Away from falling objects</b>	<b>Rock fall, landslide</b>
<b><i>Bus or other vehicles</i></b>	<b>Bring bus to stop</b>	<b>Side of road</b>	<b>Overpasses</b>
		<b>Falling debris</b>	
<b>Hold on to seat</b>	<b>Stay in bus</b>		<b>Underpasses</b> <b>Overhead Wires</b>
<b><i>In all locations</i></b>	<b>Protect oneself</b>	<b>Nearest place</b>	<b>Falling debris</b>

- 1. Emergency response personnel are likely be handicapped by impaired communications.**
- 2. Damaged and blocked transportation routes, damaged equipment, and injured personnel, are likely to be met.**
- 3. Besides protecting personnel from injury, schools, hospitals, governments, and certain businesses need to be concerned about maintaining and continuing operations after an earthquake.**
- 4. Nearly two-thirds of all businesses are expected to be non-functional.**

# What To Do After the Shaking Stops

<b>Steps</b>	<b>Specific Actions</b>	<b>Concerns</b>
<b><i>Check for injuries</i></b>	<b>Administer emergency first aid</b>	<b>Move severely injured only if mandatory Be prepared for aftershocks</b>
<b><i>Evacuate</i></b>	<b>Leave cautiously</b>	<b>Put on shoes Avoid elevators Choose exits carefully Be prepared for aftershocks</b>
<b><i>Check for safety</i></b>	<b>Turn off utilities Use flashlights no candles Account for building occupants Confine animal</b>	<b>Gas, water, electric lines may be broken Electric sparks or flame may ignite gas May need to do search and rescue Dog bites common after earthquake</b>

# What To Do After the Shaking Stops

<b>Steps</b>	<b>Specific Actions</b>	<b>Concerns</b>
<b><i>Get information</i></b>	<b>Use portable or car radio</b>	<b>Are there nearby secondary hazards, like chemical spills, fire? Avoid sightseeing, unnecessary travel, or spreading rumors</b>
<b><i>Care for and comfort others</i></b>	<b>Reassure children, ill, handicapped and elderly</b>	<b>Need physical and emotional care Avoid leaving them alone More physical and emotional trauma than other individuals</b>
<b><i>Make shelter</i></b>	<b>Use large plastic garbage bags Use blankets</b>	<b>Existing structures may be unsafe Prevent hypothermia Locate food and water</b>
